

Copilot

Yes, it's quite common to offload certain logic to a backend service, especially if it requires polyfills or other complex operations. This approach can help keep your React app lightweight and maintainable. Here are a few reasons why you might do this:

1. **Performance:** Offloading heavy computations or operations to the backend can improve the performance of your frontend app.
2. **Security:** Sensitive operations or data can be handled more securely on the server side.
3. **Compatibility:** If certain features require polyfills that might not be supported across all browsers, handling them on the backend ensures consistent behavior.
4. **Scalability:** Backend services can be scaled independently of the frontend, allowing for better resource management.

By using this approach, your React app can focus on rendering the UI and handling user interactions, while the backend takes care of the more complex logic. Does this help with your project?
